Depth First Search

Visiting the Next Node

▶ Which node do we process next in a search?

▶ BFS: the **oldest** pending node.

▶ DFS (today): the **newest** pending node.

Depth First Search

▶ In principle, use **stack** instead of **queue**.

▶ But it is easier to use recursion.

```python
def dfs(graph, u, status=None):
    """Start a DFS at `u`."""
    # initialize status if it was not passed
    if status is None:
        status = {node: 'undiscovered' for node in graph.nodes}

    status[u] = 'pending'
    for v in graph.neighbors(u): # explore edge (u, v)
        if status[v] == 'undiscovered':
            dfs(graph, v, status)
    status[u] = 'visited'
```

Example

```python
def dfs(graph, u, status=None):
    """Start a DFS at `u`."""
    # initialize status if it was not passed
    if status is None:
        status = {node: 'undiscovered' for node in graph.nodes}

    status[u] = 'pending'
    for v in graph.neighbors(u): # explore edge (u, v)
        if status[v] == 'undiscovered':
            dfs(graph, v, status)
    status[u] = 'visited'
```

Full DFS

▶ DFS will visit all nodes reachable from source.

▶ To visit all nodes in graph, need **full DFS**.

```
def full_dfs(graph):
    status = {node: 'undiscovered' for node in graph.nodes}
    for node in graph.nodes:
        if status[node] == 'undiscovered'
            dfs(graph, node, status)
```

Time Complexity

▶ In a full DFS:
  ▶ `dfs` called on each node exactly once.
  ▶ Each edge is explore exactly:
    ▶ once if directed
    ▶ twice if undirected

```python
def full_dfs(graph):
    status = {node: 'undiscovered' for node in graph.nodes}
    for node in graph.nodes:
        if status[node] == 'undiscovered'
            dfs(graph, node, status)

def dfs(graph, u, status=None):
    """Start a DFS at `u`."""
    # initialize status if it was not passed
    if status is None:
        status = {node: 'undiscovered' for node in graph.nodes}

    status[u] = 'pending'
    for v in graph.neighbors(u): # explore edge (u, v)
        if status[v] == 'undiscovered':
            dfs(graph, v, status)
    status[u] = 'visited'
```

Nesting Properties of DFS

Key Property of DFS (Informal)

▶ Between marking a node as **pending** and marking it as **visited**, other nodes nodes are marked as **pending** and **visited**.

Example

Start and Finish Times

▶ Keep a running clock (an integer).

▶ For each node, record
  ▶ **Start time**: time when marked pending
  ▶ **Finish time**: time when marked visited

▶ Increment clock whenever node is marked
  pending/visited

```python
from dataclasses import dataclass

@dataclass
class Times:
    clock: int
    start: dict
    finish: dict

def full_dfs_times(graph):
    status = {node: 'undiscovered' for node in graph.nodes}
    predecessor = {node: None for node in graph.nodes}
    times = Times(clock=0, start={}, finish={})
    for u in graph.nodes:
        if status[u] == 'undiscovered':
            dfs_times(graph, u, status, times)
    return times, predecessor

def dfs_times(graph, u, status, predecessor, times):
    times.clock += 1
    times.start[u] = times.clock
    status[u] = 'pending'
    for v in graph.neighbors(u): # explore edge (u, v)
        if status[v] == 'undiscovered':
            predecessor[v] = u
            dfs_times(graph, v, status, times)
    status[u] = 'visited'
    times.clock += 1
    times.finish[u] = times.clock
```
Example

Key Property

- ▶ Take any two nodes *u* and *v*.

- ▶ Assume for simplicity that `start[u]` ≤ `start[v]`.

- ▶ Exactly one of these is true:
  - ▶ `start[u]` ≤ `start[v]` < `finish[v]` ≤ `finish[u]`
  - ▶ `start[u]` < `finish[u]` < `start[v]` < `finish[v]`

Start and Finish Times

▶ The times encode useful information about the structure of the graph.

▶ **Example**: If *v* is reachable from the source, *u*, then `finish[v] ≤ finish[u]`.

Topological Sort

Applications of DFS

► Is node *v* reachable from node *u*?

► Is the graph connected?

► How many connected components?

► What is the shortest path between *u* and *v*? **No**.

Prerequisite Graphs

Goal: find order in which to take classes satisfying prerequisites.

Directed Acyclic Graphs

▶ A **directed cycle** is a path from a node to itself with at least one edge.

▶ A **directed acyclic graph (DAG)** is a directed graph with no directed cycles.

Example

- Prerequisite graphs are DAGs.
  - Or at least, they should be!

Topological Sorts

▶ **Given**: a DAG, $G = (V, E)$.

▶ **Compute**: an ordering of V such that if $(u, v) \in E$, then u comes before v in the ordering
▶ This is called a **topological sort** of G.

Example

MATH 18, DSC 10, DSC 40A, DSC 40B, DSC 20, DSC 30, DSC 80, CSE 151

An Algorithm

- ▶ **Recall**: If *v* is reachable from *u*, then
  `finish[v] ≤ finish[u]`.

- ▶ If *v* is reachable from *u*, *u* should come before *v*.

- ▶ Nodes with later finish times should come first.

- ▶ Algorithm:
  - ▶ Compute times with Full DFS.
  - ▶ Sort in **descending** order by finish time.

- ▶ Time complexity:

Example

Note

▶ There can be many valid topological sorts!
